Conclusions

Inheritance at the Origin of Life

- Contemporary organisms and viruses use DNA or RNA template molecules for inheritance
- These molecules are too complex to be plausible in the pre-biotic world. So how did evolution get started?
- Some Origin of Life theories envisage *metabolism based inheritance* in which proto-organisms without template molecules reproduced by growth and division
- Variations in metabolism would have led to differences in fitness that would drive evolution
- Successful variations in metabolism would have to be 'remembered' and inherited
- Questions:
 - Can a metabolic network provide the memory needed to 'remember' new solutions to the problem of 'how to survive and reproduce'
 - *How many variations are possible?* Will there be sufficient diversity to enable evolution to 'get a foothold'?

Conclusions

Biological and Chemical Computing

- A key challenge for the newer field of biological and chemical computing is the development of memory systems using components that can be readily constructed
- Such systems may be used for various purposes, including an inheritance mechanism for artificial evolution
- The simple memory mechanism being investigated here is relevant to this

Conclusions

Conceptual Background

- Metabolism based Origin of Life theories including those of Aleksandr Oparin, Stuart Kauffman, Freeman Dyson, and the Lipid World theory and GARD model of Doron Lancet's group
- Günter Wächtershäuser's chemo-autotrophic Iron-Sulphur World
- Walter Fontana's Algorithmic Chemistry
- Graham Cairns-Smith's clay crystal and genetic takeover theory
- Tibor Gánti's principles of life and chemoton theory
- Network theory, particularly the work of Sanjay Jain and Sandeep Krishna
- The Chemical Organisation Theory of Peter Dittrich and Pietro Speroni di Fenizio
- Nathaniel Virgo's 'Spots' model
- Linus Pauling's chemical bond theory

Conclusions

Objectives for this Work

- Proof of principle to show that a metabolic inheritance (memory) mechanism can support ‘substantial’ variability
- Make the system *switchable*:
 - Previous work had shown a non-switchable memory system
 - This may limit ability to adapt to a changing environment
 - Switchability is also required for IT uses

Conclusions

Molecular Structure

- *Molecules* are two dimensional rigid structures built from *Atoms* bonded together such that they occupy fixed positions on a square ‘board’
- Each square contains at most one Atom
- Each Atom Type has a defined maximum number of bonds
- Bond angles are always either 90° or 180° , and bond lengths are all equal
- Bonding is broadly consistent with valence theory
- Bond strengths are usually fixed according to the Atom Types, but some are *Perturbable*; they can be weakened or strengthened by other nearby Atoms

Conclusions

Molecular Interactions

- Molecules can Join or Split to form Molecules of different types
 - A join (eg $A + B \rightarrow C$), is a *Construction Interaction*
 - A split (eg $D \rightarrow E + F$) is called a *Fission Interaction*
- Join/Split rules are analogous real chemistry, but simpler:
 - Joining: According to valence rules. Maximize total bond energy. Atoms cannot overlap
 - Split: Break bonds with least total energy
- This allows open-ended exploration of chemical space. New Molecule Types and Interaction Types are *discovered* as the simulation runs

Conclusions

Interaction Kinetics

- Constructions and Fissions occur in a well-stirred *Reactor*
- Interaction Rates
 - Bimolecular Interaction Types: Rate = $k[R1][R2]$
 - Unimolecular Interaction Types: Rate = $k[R1]$
- Rate constants are thermodynamically realistic, using the Arrhenius equation $k = Ae^{-\frac{E_a}{RT}}$
 - E_a is the activation energy for an Interaction
 - T is temperature
 - R is the gas constant
 - A and E_a are known as the Arrhenius Parameters

Conclusions

Scenario Setup for the Example

- Define Atom Types (elements) for Carbon, Oxygen and Hydrogen
- Define Bond Strengths as for 'real' chemistry
- Add 20000 Molecules of molecular Oxygen (O_2) to the Reactor
- Add 10000 Molecules of Methane (CH_4) to the Reactor
- Add nothing else, but give names to some Molecule Types that may appear
- Limit the mass of Molecule Types that can be created to 44.1 to avoid combinatorial 'explosion'

Conclusions

Concept: Rock-Paper-Scissors

- A memory unit has three possible active states; 'Rock', 'Paper' and 'Scissors'
- 'Loopback' arrows indicate autocatalytic feedback
- Straight arrows indicate external activating stimuli
- Lines terminated with '┌' signify that activity for one state inhibits another
- Switching occurs when an external stimulus activates a new state, and simultaneously inhibits the old state
- Multiple units can co-exist in the same physical environment

Memory Unit

Atom and Bond Types

Physical Chemistry: Atom Types

Name/Symbol	Bonds	Usage / Capability
Assemblite ●	2	Used to build framework of molecular structures
Blockite (b)	4	Used to build bs ₃ 'Blocker'
Hookite (h)	4	Used to provide a 'hook' bonding site
Junctium (j)	3	Used to provide a 3 way junction in a structure
Loosium-1 (w)	2	Provides a weak (loose) bonding site for Loosium-2
Loosium-2 (x)	2	Provides a weak (loose) bonding site for Loosium-1
Metal (m)	1	Can perturb nearby Perturbium bonds, even though not bonded to Perturbium
Perturbium (p)	3	Produces bonds that can be weakened or strengthened by nearby Metal atoms
Stoppite (s)	1	Stops further growth of the Molecule at a site

Conclusions

Physical Chemistry: Bond Types

	a	h	j	b	m	p	s	w	x
a	x								
h	x								
j	x	x	x						
b									
m	x	x	x						
p	x	p	x	x					
s	x	x	x	x		p	x		
w	x		x						
x	x		x					w	

- Blank: Atoms of these types do not bond
- x: Atoms bond with Enthalpy (strength) 100
- w: Atoms bond weakly, with Enthalpy 10
- p: Perturbable Bond

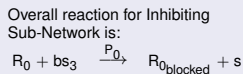

Maintenance and Inhibition of Rock State of Memory Unit 0

- R_{0pre} , m and bs_3 are 'food'
- The R_{0pre} Autocatalytic Sub-Network is activated by a short stimulus of R_0 , which enables Construction C1
- After F1, F2 and C2, an excess of R_0 is produced. The process is self-maintaining. Overall reaction:

- A later stimulus of P_0 activates the P_0 Autocatalytic Sub-Network (not shown here)
- C3 is enabled, producing $R_0 \cdot P_0$ in the Inhibiting Sub-Network
- Subsequent Interactions F3, F4 and C4 disable R_0 by converting it to $R_{0blocked}$. This 'kills' the R_{0pre} Autocatalytic Sub-Network

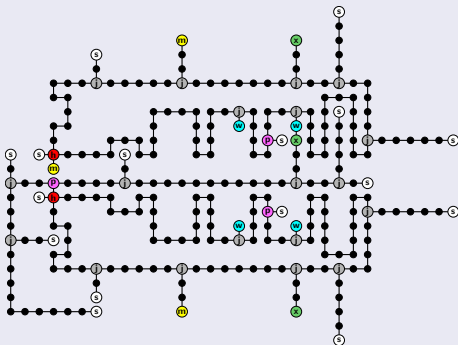

R_0 and $R_{0_{pre}}$: The Rock₀ Core Molecule Type and its Precursor

- R_0 (above) has three central recesses
- These are key to the operation of the 'Rock-Paper-Scissors' mechanism
- $R_{0_{pre}}$ (below) comprises $R_{0_{\sim m}}$ with a 'guard' that protects the recesses
- R_0 and $R_{0_{pre}}$ can join by forming a w-x (Loosium-1 / Loosium-2) bond

$R_0.R_{0_{pre}}$: The Rock₀ Precursor Splitter Complex

- The yellow metal (m) Atom on the left is close to the perturbable p-h Bond
- Bond is weakened and breaks, releasing $R_{0_{\sim m}}$
- $R_{0_{\sim m}}$ soon encounters a Metal (m) Atom, producing a new R_0 Molecule
- The loose w-x Bond also breaks, releasing the original R_0 Molecule
- Summary: An R_0 has split an $R_{0_{pre}}$ to release another R_0

Conclusions

$R_0.P_0$: Core-Core Complex for the $Rock_0$ Inhibiting Sub-Network

- P_0 (below) bonds with R_0 by forming a loose w-x Bond in the central recess of R_0
- A Metal (m) Atom is placed close to the perturbable p-s Bond in R_0 . The Bond is weakened and breaks
- This leaves a bonding site that will soon be occupied by a bs_3 'Blocker'
- Summary: A P_0 has converted an R_0 to a 'blocked' form that cannot split R_{0pre}

Design

Avoiding Interference

Memory System
Operation

Network
Architectures

Conclusions

Variations in Molecular Structure Prevent Interference Between Co-Existing Memory Units

- R_1 above, $R_{O_{pre}}$ below
- If these two Molecules joined, an 'incorrect' Precursor Splitter complex would be formed. Memory units 0 and 1 would interfere
- Joining is prevented due to variations in structure

Memory System Operation

Operation of a 5 Unit Memory System

- A system of five co-existing memory units is switched between different states
- Stimuli for P1 and P3 at time 30000 switch the system to state R0P1R2P3R4
- Other stimuli cause subsequent switches at times 50000, 60000 and 70000
- Note: These are 'stop press' results based on modified versions of the Molecule Types shown in earlier slides

Conclusions

DNA: A Genome is a Single Autocatalytic Unit

- Circles represent autocatalytic units
- Each autocatalytic unit has single strand and double strand DNA. Ie the unit has two Molecule Types, each of which can be produced from the other
- Each organism has a genome consisting of single autocatalytic unit ('Genome 2' in the example)
- (Example is for single chromosome organisms - Eg prokaryotes)

SimSoup - 1: Parallel series of Autocatalytic Units

- Figure is from ECAL 2011 paper (based on diagram from Life and Mind presentation in June 2010)
- Five 'rows' of five autocatalytic units (small circles) connected in series
- Large circles are 'food'
- Each row can have between one and five active units
- Output of one unit is required as a prerequisite for activation of the next unit
- Shaded units are active. Figure shows 'genome' 43102
- Each row can be in 6 alternative states
- Network as a whole can have $6^5 = 7776$ different states
- Drawback: Memory units are not switchable

SimSoup - 2: Independent Groups of Autocatalytic Units

- A 'genome' is defined by the state of multiple independent switchable memory units
- Each memory unit has three autocatalytic (sub) units
- Each memory unit has only one active autocatalytic (sub) unit (except during switching)
- Figure shows 'genome' $R_0S_1P_2P_3S_4$

The GARD Beta Matrix Denoting Catalytic Effect

Figures omitted from the Web version of this presentation for copyright reasons.

The paper is available at:

http://www.mitpressjournals.org/doi/pdf/10.1162/artl_a_00064

Refer to Figures 1 and 2a in the paper.

- Figures are from 'Excess Mutual Catalysis Is Required for Effective Evolvability', Markovitch and Lancet, 2012
- Top diagrams: Arrows show the increase in rate of production of one species due catalytic effect of another
- The underlying reactions are not explicitly modelled
- a) Excess mutual catalysis.
b) Excess self-catalysis
- Lower diagram: Number of alternative 'compotypes' (analogous with genotypes) is typically between 1 and 6
- So diversity is limited
- Due to random connectivity?

Multiple Autocatalytic Cores

Figure omitted from the Web version of this presentation for copyright reasons.

The paper is available at:
<http://www.biologydirect.com/content/pdf/1745-6150-7-1.pdf>
 Refer to Figure 2 in the paper.

- Figure is from 'Evolution Without Genes': Vasas, Fernando, Santos, Kauffman and Szathmáry, 2012
- There are two separate autocatalytic 'cores'
- The first consists of two loops: $A \rightarrow A$ and $A \rightarrow B \rightarrow A$
- The second consists of the two loops $C \rightarrow C$ and $C \rightarrow D \rightarrow E \rightarrow C$
- Each of these two cores is a (non-switchable) autocatalytic memory unit
- The paper concludes that autocatalytic cores can be seen as (one bit) units of evolution

Conclusions

- Results suggest that chemical memory is possible. A five unit switchable system with 243 alternative states has been designed and simulated
- The design supports systems with more units. A ten unit system would have $3^{10} = 59049$ states
- The system is simpler than RNA/DNA based systems (complexity measure: number of slides needed to describe)
- It is nonetheless highly non-random and modularised
- The following questions can be asked:
 - What network and molecular architectures would be prebiotically plausible and also lead to substantial variability?
 - Can low specificity molecules support substantial variability?
